

- 1 -

**PROCESS FOR PRODUCING TYRES, TYRES THUS OBTAINED AND
ELASTOMERIC COMPOSITIONS USED THEREIN**

The present invention relates to a process for
5 producing tyres for vehicle wheels, to the tyres thus
obtained and to the crosslinkable elastomeric
compositions used therein. More particularly, the
present invention relates to a process for producing
10 tyres for vehicle wheels, which can be carried out in
substantial absence of conventional crosslinking
agents, to the tyres thus obtained and to the
crosslinkable compositions used therein.

Processes for vulcanizing diene elastomers with
sulphur are widely used in the rubber industry for the
15 production of a wide range of products, and in
particular tyres for vehicle wheels. Implementation of
these processes, although giving high-quality
vulcanized products, shows a considerable complexity,
mainly due to the fact that, to obtain optimum
20 vulcanization within industrially acceptable times, it
is necessary to use a complex vulcanizing system which
includes, besides sulphur or sulphur-donating
compounds, one or more activators (for example stearic
acid, zinc oxide and the like) and one or more
25 accelerators (for example thiazoles, dithiocarbamates,
thiurams, guanidines, sulphenamides and the like). The
presence of these products can, in some cases, entail
considerable problems in terms of harmfulness/toxicity
both during production and during use, in particular
30 when the vulcanized products are intended for
medical/health-care or food use. In addition, it is
known that the use of sulphur or sulphur-donating
compounds leads, during the vulcanization step which is
generally carried out at temperatures above 150°C, to
35 development of volatile sulphur-containing compounds.

Consequently, in recent years, research efforts
have been directed along two different lines, the first

- 2 -

being to improve the known vulcanization processes to make them more efficient and cleaner, the second aimed at developing alternative crosslinking techniques. Although appreciable progress has been made, it is not possible to state at the present time that alternative techniques to crosslinking with sulphur exist which would give similar results and would simultaneously afford an effective simplification in terms of production. For example, crosslinking processes via peroxide compounds require special precautions on account of the instability of these compounds, in addition to requiring the use of activators. Crosslinking by means of radiation involves use of complex equipment, as well as incorporation of all the precautions required when high-energy and high-power radiation is used.

So-called "self-crosslinking" elastomeric compositions, i.e. compositions which do not require the use of crosslinking agents such as sulphur or sulphur compounds, are known in the art.

For example, US patent 2,724,707 describes elastomeric compositions consisting of a diene polymer containing carboxylic groups, in particular a carboxylated nitrile rubber (XNBR) obtained by partial hydrolysis of a butadiene/acrylonitrile polymer, wherein a polyhydric metal oxide (for example zinc oxide) is dispersed. On heating these compositions, they crosslink according to a mechanism of ionic type.

A study on crosslinking of XNBR having a high carboxylation degree by reaction with an epoxy resin (for example bisphenol A diglycidyl ether) in the presence of reinforcing fillers such as carbon black, silica and clay, is reported in the article by S.K. Chakraborty and S.K. De, published in the *Journal of Applied Polymer Science*, Vol. 27, pp. 4561-4576 (1982).

The crosslinking is carried out by heating the rubber compound to 150°-180°C. As known, epoxy resins are low molecular weight products wherein the epoxide (or oxirane) groups are "external", i.e. they are located

5 in a terminal position on the main hydrocarbon chain, the oxygen atom forming the oxirane ring being linked to the last and the penultimate carbon atom of this chain.

A study of the crosslinking of a composition 10 based on epoxidized natural rubber (ENR) and XNBR is reported in the article by R. Alex, P.P. De, N.M. Mathew and S.K. De, published in *Plastics and Rubber Processing and Applications*, Vol. 14, No. 4, 1990. In particular, this article describes the crosslinking of 15 compositions consisting of ENR and XNBR as such or containing silica or carbon black as reinforcing filler. According to what reported by the authors, in the mixtures of ENR and XNBR the crosslinking reaction implies the formation of ester bonds between the 20 epoxide groups and carboxylic groups. The rheometric curves would show absence of reversion, stability of the crosslinked structure and a high crosslinking degree.

Italian patent IT-1,245,551 describes self- 25 crosslinking compositions containing an epoxidized elastomer and a crosslinking agent of formula R1-R-R2, wherein R is an arylene, alkylene or alkenylene group, while R1 and R2 are carboxylic, amine, sulphonic or chlorosulphonic groups. Dicarboxylic or polycarboxylic 30 acids, or mixtures thereof, can be used as crosslinking agents. Self-crosslinking compositions containing an epoxidized elastomer and a second elastomer wherein the repeating units of the polymer chain contain at least one carboxylic group are also described. For example, 35 self-crosslinking compositions are obtained by mixing

- 4 -

an epoxidized elastomer (for example the products ENR 25 or ENR 50 which are available under the brand name Epoxiprene® from the Malaysian Rubber Producers Research Association) with a butadiene/ acrylic acid 5 copolymer (for example a product sold by Polysar/Bayer under the brand name Krynnac®). The crosslinking reaction takes place by heating between the epoxide groups and the carboxylic groups, with formation of ester bonds.

10 US patent 5,173,557 describes self-crosslinking compositions comprising an elastomeric polymer functionalized with isocyanate groups and a compound containing at least two active hydrogen atoms of Zerewitinoff type, or self-crosslinking compositions 15 comprising an elastomeric polymer containing active hydrogen atoms of Zerewitinoff type and a compound containing at least two isocyanate groups. Alternatively, an elastomeric polymer containing either 20 isocyanate groups or active hydrogens of Zerewitinoff type can be used, without using an additional crosslinking agent. The active hydrogen atoms can be present, for example, on hydroxide, amine, carboxylic or thiol groups. To avoid undesired pre-crosslinking of the elastomer, the isocyanate groups are blocked 25 beforehand with suitable functional groups, which are removed by heating before the crosslinking reaction between the free isocyanate groups and the active hydrogens, optionally with the aid of a catalyst.

30 On the basis of the Applicant's experience, the self-crosslinking compositions proposed hitherto in the prior art do not provide a valid alternative to conventional compositions vulcanized with sulphur or derivatives thereof. The reason for this is that the performance qualities of the crosslinked products are 35 generally unsatisfactory, in particular for

applications such as tyre rubber compounds, wherein a substantial constancy of the elastic performance qualities over a wide range of working temperatures and at the same time high abrasion resistance without
5 unacceptably increasing hardness is required. This is the case, for example, for the self-crosslinking compositions described above wherein a polymer containing carboxylic groups (for example XNBR) is crosslinked by heating in admixture with an epoxidized
10 elastomeric polymer or with an epoxy resin.

The Applicant has now found that crosslinked products, and in particular tyres for vehicle wheels, which have the desired combination of properties can be produced in the substantial absence of additional
15 crosslinking agents, by using self-crosslinking compositions comprising a mixture of an elastomeric polymer containing carboxylic groups and a liquid organic compound containing epoxide groups located internally on the molecule.

20 After heating, these compositions achieve a high degree of crosslinking without addition of conventional crosslinking agents, with crosslinking times contained within limits which are acceptable for industrial use. The resulting crosslinked product
25 combines excellent mechanical and elastic performance qualities (in particular stress at break, elongation at break, modulus and hardness) with low values of abrasability, so as to make the self-crosslinking compositions above particularly suitable as elastomeric
30 materials to be used for the production of tyres, in particular tread bands.

In addition, the use of liquid compounds containing internal epoxide groups makes it possible to obtain crosslinkable compositions which have excellent
35 processability and a high capacity to include

- 6 -

reinforcing fillers, even in the absence of compatibilizing additives, since these epoxidized products act not only as crosslinking agents but also as processing coadjuvants and are capable of 5 interacting with reinforcing fillers containing active hydroxyl groups (for example silica), thus favouring compatibilization with the polymer matrix.

According to a first aspect, the present invention thus relates to a process for producing tyres 10 for vehicle wheels, the said process comprising the following steps:

manufacturing a green tyre comprising at least one crosslinkable elastomeric material;

15 subjecting the green tyre to moulding in a mould cavity defined in a vulcanization mould;

crosslinking the elastomeric material by heating the tyre to a predetermined temperature and for a predetermined time;

20 characterized in that the crosslinkable elastomeric material comprises: (a) an elastomeric polymer containing carboxylic groups, and (b) an epoxidized liquid organic compound containing epoxide groups located internally on the molecule, the said crosslinking step being carried out 25 substantially in the absence of additional crosslinking agents.

According to a further preferred aspect, the crosslinking step is carried out by heating the crosslinkable elastomeric material to a temperature of 30 at least 120°C, preferably of at least 160°C, for a time of at least 3 minutes, preferably of at least 10 minutes.

In accordance with a particularly preferred aspect, the said crosslinkable elastomeric material 35 also comprises a reinforcing filler.

- 7 -

In a second aspect, the present invention relates to a tyre for vehicle wheels comprising one or more components made of a crosslinked elastomeric material, characterized in that at least one of the 5 said components comprises, as crosslinked elastomeric material, an elastomeric polymer containing carboxylic groups crosslinked by reaction with an epoxidized liquid organic compound containing epoxide groups located internally on the molecule, wherein the said 10 carboxylated elastomeric polymer is crosslinked substantially in the absence of additional crosslinking agents.

According to a further aspect, the present invention relates to a tyre for vehicles, comprising a 15 belt structure extended coaxially around a carcass structure and a tread band extended coaxially around the belt structure and having an external rolling surface intended to come into contact with the ground, characterized in that the said tread band comprises an 20 elastomeric polymer containing carboxylic groups crosslinked by reaction with an epoxidized liquid organic compound containing epoxide groups located internally on the molecule, and wherein the said carboxylated elastomeric polymer is crosslinked 25 substantially in the absence of additional crosslinking agents.

According to a further aspect, the present invention relates to a crosslinkable elastomeric composition comprising: (a) an elastomeric polymer 30 containing carboxylic groups; and (b) a liquid organic compound containing epoxide groups located internally on the molecule; the said composition being crosslinkable in substantial absence of any additional crosslinking agents.

- 8 -

According to a further aspect, the present invention relates to a crosslinked elastomeric product obtained by crosslinking a crosslinkable composition as defined above.

5 For the purposes of the present description and the claims, the expression "in substantial absence of any additional crosslinking agents" means that the crosslinkable composition is not subjected to the action of other systems capable of bringing about its crosslinking, or that other products which may be present in the composition can in themselves participate in the crosslinking reaction, but are used in amounts less than the minimum amount required to obtain an appreciable degree of crosslinking in short 10 times (for example within 5 minutes). In particular, the compositions according to the present invention are crosslinkable in substantial absence of any of the crosslinking systems commonly used in the art, such as, for example, sulphur or sulphur donors, peroxides or 15 other radical initiators, and neither are these compositions subjected to the action of high-energy 20 radiation (UV, gamma rays, etc.) so as to induce crosslinking phenomena in the polymer.

The liquid organic compounds containing epoxide 25 groups located internally on the molecule (for simplicity, these are referred to hereinbelow as "organic compounds containing internal epoxide groups" or "epoxidized organic compounds") are products of hydrocarbon type which are, at room temperature, in the 30 form of viscous liquids or oils.

These compounds contain at least two internal epoxide groups, i.e. groups wherein one oxirane bridge connects:

35 (i) two adjacent carbon atoms located on the main chain, with the condition that neither of the said two

- 9 -

adjacent carbon atoms is a terminal carbon atom of this chain; or

(ii) two adjacent carbon atoms located on a side chain.

5 . The presence of internal epoxide groups does not, however, exclude the possibility of epoxide groups in a terminal position also being present in the molecule.

10 At least two internal epoxide groups are present in the liquid organic compounds according to the present invention. In general, the amount of epoxide groups is such that the epoxide equivalent weight of the epoxidized compound is usually between 40 and 2,000, preferably between 50 and 1,500, more preferably between 100 and 1,000. With the term "epoxide equivalent weight" (EEW) it is meant the molecular weight of the epoxidized compound per mole of oxirane oxygen, namely:

$$\text{EEW} = \frac{1600}{\%O}$$

20 where %O is the content of oxirane oxygen, expressed as a percentage by weight of oxirane oxygen relative to the total weight of the compound. The content of oxirane oxygen in the epoxidized compounds can be determined according to known techniques, for example 25 by titration with a solution of hydrobromic acid in acetic acid.

One class of liquid organic compounds containing internal epoxide groups which are particularly preferred is that of epoxidized oils, 30 which can be obtained by epoxidation of unsaturated fatty acids or esters (in particular glycerides, diglycerides or triglycerides) of unsaturated fatty acids, of synthetic or natural origin, or alternatively by epoxidation of mixtures of the said unsaturated

- 10 -

acids or esters with saturated acids or esters thereof. The saturated or unsaturated fatty acids generally contain from 10 to 26 carbon atoms, preferably from 14 to 22 carbon atoms. Examples of unsaturated fatty acids 5 are: myristoleic acid, palmitoleic acid, oleic acid, gadoleic acid, erucic acid, ricinoleic acid, linoleic acid, linolenic acid, arachidonic acid and the like, or mixtures thereof. Examples of saturated fatty acids are: lauric acid, myristic acid, palmitic acid, stearic acid, behenic acid and the like, or mixtures thereof. 10 Plant oils such as, for example: epoxidized linseed oil, epoxidized safflower oil, epoxidized soybean oil, epoxidized corn oil, epoxidized cottonseed oil, epoxidized rapeseed oil, epoxidized castor oil, 15 epoxidized tung oil, epoxidized tall oil, octyl epoxytallate, epoxidized sunflower oil, epoxidized olive oil and the like, or mixtures thereof, are particularly preferred. The epoxidized oils generally have a freezing temperature of less than 23°C, preferably less than 10°C. Products of this type can be found on the market, for example, under the brand names 20 Epoxol® (FACI, American Chemical Service Inc.); Paraplex®, Plasthall® and Monoplex® (C.P. Hall); Vikoflex® and Ecepox® (Elf Atochem).

25 Another class of liquid organic compounds containing internal epoxide groups which can be used advantageously according to the present invention consists of epoxidized diene oligomers, wherein the base polymer structure, of synthetic or natural origin, 30 is derived from one or more conjugated diene monomers, optionally copolymerized with other monomers containing ethylenic unsaturation. These oligomers generally have an average molecular weight (number-average), which can be determined, for example, by gel permeation

- 11 -

chromatography (GPC), of between 500 and 10,000, preferably between 1,000 and 8,000.

Oligomers derived from the (co)polymerization of conjugated diene monomers containing from 4 to 12, 5 preferably from 4 to 8, carbon atoms, selected, for example, from: 1,3-butadiene, isoprene, chloroprene, 2,3-dimethyl-1,3-butadiene, 3-butyl-1,3-octadiene, 2-phenyl-1,3-butadiene and the like, or mixtures thereof, are particularly preferred. 1,3-Butadiene and isoprene 10 are particularly preferred.

The diene monomers can optionally be copolymerized with other monomers containing ethylenic unsaturation, such as, for example: alpha-olefins containing from 2 to 12 carbon atoms (for example 15 ethylene, propylene or 1-butene), monovinylarenes containing from 8 to 20 carbon atoms (for example styrene, 1-vinylnaphthalene or 3-methylstyrene), vinyl esters wherein the ester group contains from 2 to 8 carbon atoms (for example vinyl acetate, vinyl 20 propionate or vinyl butanoate), alkyl acrylates and alkyl methacrylates wherein the alkyl contains from 1 to 8 carbon atoms (for example ethyl acrylate, methyl acrylate, methyl methacrylate, tert-butyl acrylate or n-butyl acrylate), acrylonitrile, and the like, or 25 mixtures thereof.

Among the epoxidized diene oligomers, preferred are those obtained by epoxidation of oligomers of: 1,3-butadiene; isoprene; 1,3-butadiene and styrene; 1,3-butadiene and isoprene; isoprene and styrene; 1,3- 30 butadiene and acrylonitrile; and the like. Epoxidized oligomers of 1,3-butadiene or of isoprene are particularly preferred.

Epoxidized diene oligomers which can be used in the present invention are commercially available, for 35 example under the brand name Poly BD® from Elf Atochem.

The epoxidation reaction of a compound containing internal alkylene groups can be carried out according to known techniques. For example, the starting material can be subjected to direct oxidation 5 using a suitable oxidizing agent such as a peracid (in particular perbenzoic acid, metachloroperbenzoic acid, peracetic acid, trifluoroperacetic acid, perpropionic acid, and the like) or an alkaline oxidizing agent (for example hydrogen peroxide mixed with aqueous sodium 10 hydroxide solution), or alternatively by reaction with oxygen gas in the presence of a catalyst (for example Ag). Alternatively, it is possible to carry out a selective oxidation reaction of the internal alkylene groups by formation of a halohydrin by reaction with a 15 halogen (for example Cl₂ or Br₂) in the presence of water, followed by alkaline treatment with formation of the epoxide groups. Further details regarding the epoxidation reactions are given, for example, in US 20 patents 4,341,672, 4,851,556 and 5,366,846.

The elastomeric polymers containing carboxylic groups (also referred to for simplicity hereinbelow as "carboxylated elastomeric polymers") which can be used in accordance with the present invention are homopolymers or copolymers with elastomeric properties, 25 which have a glass transition temperature (T_g) of less than 23°C, preferably less than 0°C, and which contain at least 0.1 mol%, preferably from 1 to 30 mol% and even more preferably from 2 to 10 mol%, of carboxylic groups relative to the total number of moles of 30 monomers present in the polymer. Mixtures of various polymers containing carboxylic groups, or mixtures of one or more carboxylated polymers with one or more non-carboxylated elastomeric polymers, also fall within the present definition.

- 13 -

In the case of copolymers, these can have a random, blocked, grafted, or also mixed, structure. The average molecular weight of the base polymer is preferably between 2,000 and 1,000,000, preferably 5 between 50,000 and 500,000.

Carboxylated diene homopolymers or copolymers wherein the base polymer structure, of synthetic or natural origin, is derived from one or more conjugated diene monomers, optionally copolymerized with 10 monovinylarenes and/or polar comonomers, are particularly preferred. Preferably, the base polymer structure is obtained by (co)polymerization of diene monomers containing from 4 to 12, preferably from 4 to 15 8, carbon atoms, selected, for example, from: 1,3-butadiene, isoprene, 2,3-dimethyl-1,3-butadiene, 3-butyl-1,3-octadiene, 2-phenyl-1,3-butadiene and the like, or mixtures thereof. 1,3-Butadiene and isoprene are particularly preferred.

Monovinylarenes which can optionally be used as comonomers generally contain from 8 to 20, preferably from 8 to 12, carbon atoms and can be selected, for example, from: styrene; 1-vinylnaphthalene; 2-vinyl-naphthalene; various alkyl, cycloalkyl, aryl, alkylaryl or arylalkyl derivatives of styrene, such as, for example: 3-methylstyrene, 4-propylstyrene, 4-cyclohexylstyrene, 4-dodecylstyrene, 2-ethyl-4-benzylstyrene, 4-p-tolylstyrene, 4-(4-phenylbutyl)styrene and the like, or mixtures thereof. Styrene is particularly preferred. These monovinylarenes can optionally be substituted with one or more functional groups, such as alkoxy groups, for example 4-methoxystyrene, amino groups, for example 4-dimethylaminostyrene, and the like.

Various polar comonomers can be introduced into 35 the base polymer structure, in particular

vinylpyridine, vinylquinoline, acrylic and alkylacrylic acid esters, nitriles and the like, or mixtures thereof, such as, for example: methyl acrylate, ethyl acrylate, methyl methacrylate, ethyl methacrylate and 5 acrylonitrile.

Among the base polymer structures which are particularly preferred are: natural rubber, polybutadiene, polyisoprene, styrene/butadiene copolymers, butadiene/isoprene copolymers, 10 styrene/isoprene copolymers, butadiene/acrylonitrile copolymers and the like, or mixtures thereof.

In the case of base structures of copolymer type, the amount of diene comonomer relative to the other comonomers is such as to ensure that the final 15 polymer has elastomeric properties. In this respect, it is not possible generally to establish the minimum amount of diene comonomer required to obtain the desired elastomeric properties. As an indication, an amount of diene comonomer of at least 50% by weight 20 relative to the total weight of the comonomers can generally be considered sufficient.

The preparation of the base polymer can be carried out according to known techniques, generally by (co)polymerization of the corresponding monomers in 25 emulsion, in suspension or in solution.

To introduce carboxylic groups, the base polymer thus obtained can be made to react with a carboxylating agent in the presence of a radical initiator, preferably an organic peroxide (for example 30 dicumyl peroxide or benzoyl peroxide). Carboxylating agents commonly used are, for example: maleic anhydride, itaconic anhydride, thioglycolic acid, beta-mercaptopropionic acid and the like.

The introduction of carboxylic groups can also 35 be carried out during the synthesis of the polymer by

- 15 -

copolymerization between a conjugated diene, optionally mixed with monovinylarenes and/or polar comonomers, as reported above, and an olefinic monomer containing one or more carboxylic groups, or a derivative thereof.

5 Carboxylated olefinic monomers usually used are, for example: acrylic acid, methacrylic acid, sorbic acid, beta-acryloxypropanoic acid, ethacrylic acid, 2-ethyl-3-propylacrylic acid, vinylacrylic acid, itaconic acid, cinnamic acid, maleic acid, fumaric acid and the like, 10 or mixtures thereof. Within this class of carboxylated elastomeric polymers, the following are particularly preferred: 1,3-butadiene/(meth)acrylic acid copolymers, 1,3-butadiene/acrylonitrile/(meth)acrylic acid copolymers, 1,3-butadiene/styrene/(meth)acrylic acid copolymers and the like, or mixtures thereof.

15 Alternatively, the corresponding carboxylic derivatives can be used, in particular anhydrides, esters, nitriles or amides. In this case, the polymer obtained is then subjected to hydrolysis so as to convert, partially or totally, the functional groups thus introduced into free carboxylic groups.

20 Carboxylated elastomeric polymers which may also be used are elastomeric copolymers of one or more monoolefins with an olefinic comonomer containing one 25 or more carboxylic groups or derivatives thereof. The monoolefins can be selected from: ethylene and alpha-olefins generally containing from 3 to 12 carbon atoms, such as, for example: propylene, 1-butene, 1-pentene, 1-hexene, 1-octene and the like, or mixtures thereof. 30 The following are preferred: copolymers between ethylene and an alpha-olefin, and optionally a diene; homopolymers of isobutene or copolymers thereof with small amounts of a diene, which are optionally at least partially halogenated. The optional diene contains, in 35 general, from 4 to 20 carbon atoms, and is preferably

- 16 -

selected from: 1,3-butadiene, isoprene, 1,4-hexadiene, 1,4-cyclohexadiene, 5-ethylidene-2-norbornene, 5-methylene-2-norbornene, and the like. Among these, the following are particularly preferred: ethylene/5 propylene copolymers (EPR) or ethylene/propylene/diene copolymers (EPDM); polyisobutene; butyl rubbers; halobutyl rubbers, in particular chlorobutyl or bromobutyl rubbers; and the like, or mixtures thereof. Carboxylated olefinic comonomers can be selected from those mentioned above for the diene polymers. When a diene comonomer is present, it can be used to introduce carboxylic groups by means of the carboxylation reaction as described above.

Further information regarding structure and production processes of carboxylated elastomers are given, for example, in the article by H.P. Brown in *Rubber Chemistry and Technology*, Vol. XXX, 5, page 1347 et seq (1957) or also in US patent 2,724,707.

Examples of carboxylated elastomeric polymers which can be used in the present invention and which are currently commercially available are the products Nipol® EP (Nippon Zeon) or the products of the series Krymact® X (Bayer).

In accordance with the present invention, the epoxidized liquid compound is mixed with the carboxylated elastomeric polymer in proportions which vary as a function of the amount of functional groups present and as a function of the elastic properties which it is desired to obtain for the final product. In general, the amount of epoxidized liquid compound can range between 5 and 200 parts by weight, preferably between 10 and 120 parts by weight, per 100 parts by weight of elastomeric polymer.

The crosslinkable compositions according to the present invention can contain reinforcing fillers, in

- 17 -

an amount generally of between 20 and 120 phr, preferably between 40 and 90 phr (phr = parts by weight per 100 parts of polymer base). The reinforcing filler can be selected from those commonly used for 5 crosslinked products, and in particular for tyres, such as: carbon black, silica, alumina, aluminosilicates, calcium carbonate, kaolin and the like, or mixtures thereof.

The crosslinkable compositions according to the 10 present invention can comprise other commonly used additives selected on the basis of the specific application for which they are intended. For example, the following can be added to these compositions: 15 antioxidants, protective agents, plasticizers, compatibilizing agents for the reinforcing filler, adhesives, anti-ozone agents, modifying resins, fibres (for example Kevlar® pulp) and the like.

In particular, for the purpose of further 20 improving processability, a lubricant can be added to the crosslinkable compositions according to the present invention, this lubricant being selected in general from mineral oils, vegetable oils, synthetic oils and the like, or mixtures thereof, for example: aromatic 25 oil, naphthenic oil, phthalic oil, soybean oil and the like. The amount of lubricant can range in general from 2 to 100 phr, preferably from 5 to 50 phr.

For the purpose of increasing the crosslinking 30 rate, an effective amount of a condensation catalyst can also be added to the crosslinkable compositions according to the present invention. This amount may vary within a wide range, and is generally between 0.01 and 5 parts by weight, preferably between 0.1 and 3 parts by weight, relative to 100 parts by weight of carboxylated elastomeric polymer. The catalyst can be

selected from those known in the art for condensation reactions, and in particular:

- carboxylates of metals such as tin, zinc, zirconium, iron, lead, cobalt, barium, calcium, manganese and the like, for example: dibutyltin dilaurate, dibutyltin diacetate, dioctyltin dilaurate, stannous acetate, stannous caprylate, lead naphthenate, zinc caprylate, zinc naphthenate, cobalt naphthenate, ferrous octanoate, iron 2-ethylhexanoate, and the like;

- arylsulphonic acids or derivatives thereof, for example: p-dodecylbenzenesulphonic acid, tetrapropylbenzenesulphonic acid, acetyl p-dodecylbenzenesulphonate, 1-naphthalene sulphonic acid, 2-naphthalene sulphonic acid, acetyl methyl sulphonate, acetyl p-toluenesulphonate, and the like;

- strong inorganic acids or bases, such as sodium hydroxide, potassium hydroxide, hydrochloric acid, sulphuric acid and the like;

- amines and alkanolamines, for example ethylamine, dibutylamine, hexylamine, pyridine, dimethylethanolamine and the like;

or mixtures thereof.

The crosslinkable compositions according to the present invention can be prepared by mixing the polymer base and the reinforcing filler optionally present and the other additives according to techniques known in the art. The mixing can be carried out, for example, using an open-mill mixer, or an internal mixer of the type with tangential rotors (Banbury) or interlocking rotors (Intermix), or in continuous mixers of the Ko-Kneader (Buss) or co-rotating or counter-rotating twin-screw type.

During the mixing, the temperature is kept below a predetermined value so as to avoid premature crosslinking of the composition. To this end, the

- 19 -

temperature is generally kept below 170°C, preferably below 150°C, even more preferably below 120°C. As regards the mixing temperature, this can vary within a wide range, depending mainly on the specific
5 composition of the mixture, on the presence of any fillers and on the type of mixer used. In general, a mixing time of more than 90 sec, preferably between 3 and 35 min, is sufficient to obtain a homogeneous composition.

10 In order to optimize the dispersion of the filler while keeping the temperature below the values indicated above, multi-step mixing processes can also be employed, optionally using a combination of different mixers arranged in series.

15 As an alternative to the abovementioned solid-state mixing processes, in order to improve the dispersion of the components, the crosslinkable compositions according to the present invention can advantageously be prepared by mixing the epoxidized
20 liquid compound, and optionally the reinforcing filler and the other additives, with the polymer base in the form of an aqueous emulsion or a solution in an organic solvent. The filler can be used as such or in the form of a suspension or dispersion in an aqueous medium. The
25 polymer is subsequently separated from the solvent or from the water by suitable means. For example, when a polymer in emulsion is used, the polymer can be precipitated in the form of particles including the oily phase and any filler by adding a coagulant. A
30 coagulant which can be used in particular is an electrolytic solution, for example an aqueous sodium or potassium silicate solution. The coagulation process can be promoted by using a volatile organic solvent which is then removed by evaporation during
35 precipitation of the filled polymer. Further details

- 20 -

regarding processes of this type for the preparation of elastomeric compositions are given, for example, in US patent 3,846,365.

5 The present invention will now be illustrated in further detail by means of a number of working examples, with reference to:

the attached Figure 1, which is a view in cross section with partial cutaway of a tyre according to the present invention.

10 With reference to Fig. 1, a tyre 1 conventionally comprises at least one carcass ply 2 whose opposite side edges are externally folded around respective anchoring bead wires 3, each enclosed in a bead 4 defined along an inner circumferential edge of the tyre, with which the tyre engages on a wheel rim 5 forming part of the wheel of a vehicle.

15 Along the circumferential development of the carcass ply 2 are applied one or more belt strips 6, made using metal or textile cords enclosed in a rubber sheet. Outside the carcass ply 2, in respective opposite side portions of this ply, there is also applied a pair of side walls 7, each of which extends from the bead 4 to a so-called "shoulder" region 8 of the tyre, defined by the opposing ends of the belt 20 strips 6. On the belt strips 6 is circumferentially applied a tread band 9 whose side edges end at the shoulders 8, joining it to the side walls 7. The tread band 9 externally has a rolling surface 9a, designed to come into contact with the ground, in which 25 circumferential grooves 10 can be provided, intercalated with transverse cuttings, not shown in the attached figure, which define a plurality of blocks 11 variously distributed on the said rolling surface 9a.

30 The process for producing the tyre according to the present invention can be carried out according to 35

techniques and using apparatus known in the art (see, for example, patents EP-199,064, US-4,872,822 and US-4,768,937). More particularly, this process comprises a 5 step of manufacturing the green tyre, in which a series of semi-finished articles, prepared beforehand and separately from each other and corresponding to the various parts of the tyre (carcass plies, belt strips, bead wires, fillers, side walls and tread bands) are combined together using a suitable manufacturing 10 machine.

The green tyre thus obtained is then subjected to the subsequent steps of moulding and crosslinking. To this end, a vulcanization mould is used which is 15 designed to receive the tyre being processed inside a moulding cavity having walls which are countermoulded to the outer surface of the tyre when the crosslinking is complete.

The green tyre can be moulded by introducing a 20 pressurized fluid into the space defined by the inner surface of the tyre, so as to press the outer surface of the green tyre against the walls of the moulding cavity. In one of the moulding methods widely practised, a vulcanization chamber made of elastomeric 25 material, filled with steam and/or another fluid under pressure, is inflated inside the tyre closed inside the moulding cavity. In this way, the green tyre is pushed against the inner walls of the moulding cavity, thus obtaining the desired moulding. Alternatively, the moulding can be carried out without an inflatable 30 vulcanization chamber, by providing inside the tyre a toroidal metal support shaped according to the configuration of the inner surface of the tyre to be obtained (see, for example, patent EP-242,840). The difference in coefficient of thermal expansion between 35 the toroidal metal support and the crude elastomeric

- 22 -

material is exploited to achieve an adequate moulding pressure.

At this point, the step of crosslinking of the crude elastomeric material present in the tyre is carried out. To this end, the outer wall of the vulcanization mould is placed in contact with a heating fluid (generally steam) such that the outer wall reaches a maximum temperature generally of between 100°C and 230°C. Simultaneously, the inner surface of the tyre is brought to the crosslinking temperature using the same pressurized fluid used to press the tyre against the walls of the moulding cavity, heated to a maximum temperature of between 100 and 250°C. The time required to obtain a satisfactory degree of crosslinking throughout the mass of the elastomeric material can vary in general between 3 min and 90 min and depends mainly on the dimensions of the tyre.

The present invention will now be illustrated in further detail by means of a number of preparation examples.

EXAMPLES 1-6

The compositions given in Table 1 were prepared using an open cylinder mixer, with a mixing time of about 30 min, taking care to keep the temperature as low as possible and, in any event, not above 120°C.

The compositions thus prepared were subjected to MDR rheometric analysis using an MDR rhometer from Monsanto, the tests being carried out at 200°C for 30 min, with an oscillation frequency of 1.66 Hz (100 oscillations per minute) and an oscillation amplitude of $\pm 0.5^\circ$. The mechanical properties (according to ISO standard 37) and the hardness in IRHD degrees (according to ISO standard 48) were measured on samples of the said compositions crosslinked at 200°C for 15 min. The results are given in Table 1.

10 Nipol EP® 1072 (Nippon Zeon): acrylonitrile/butadiene/carboxylate monomer terpolymer containing 28% by weight of acrylonitrile and 7.5% by weight of carboxylic groups;

Paraplex® G-60 (C.P. Hall): epoxidized soybean oil having:

- 24 -

freezing point = 5°C, average molecular weight = 1,000
and epoxide equivalent weight = 210;

Poly BD® 600 (Elf Atochem): epoxidized polybutadiene with
hydroxyl end groups (2.4 meq/g of hydroxyls) having:

5 average molecular weight = 2,600, epoxide equivalent
weight = 460 (configuration of epoxidized double bonds:
16% cis, 57% trans; 26% of epoxidized vinyl double
bonds);

Poly BD® 605 (Elf Atochem): epoxidized polybutadiene with
10 hydroxyl end groups (2.5 meq/g of hydroxyls) having:
average molecular weight = 2,600, epoxide equivalent
weight = 260 (configuration of epoxidized double bonds:
15% cis, 55% trans; 30% of epoxidized vinyl double
bonds).

15 As regards Examples 1 and 2 (comparative),
there was essentially no crosslinking or in any event
not enough to allow the preparation of test pieces. For
this reason, the tensile properties have not been
20 reported.

The examples given in Table 1 demonstrate that,
with the compositions according to the invention,
comprising a carboxylated polymer mixed with a liquid
25 epoxidized compound, it is possible to achieve a high
degree of crosslinking in short times without the
addition of any conventional crosslinking system. The
crosslinking does not take place either by using a
30 polymer of similar structure but not carboxylated mixed
with the same epoxidized compound, or by heating the
carboxylated polymer alone.

EXAMPLES 7-13

The compositions given in Table 2 were prepared
using the same open mixer as in Examples 1-6, with a
mixing time of about 30 min, the maximum temperature
35 reached being 100°C.

- 25 -

The compositions thus prepared were subjected to MDR rheometric analysis using the same rheometer and under the same conditions as in Examples 1-6.

5 The mechanical properties (according to ISO standard 37) and the hardness in IRHD degrees (according to ISO standard 48) were measured on samples of the abovementioned compositions crosslinked at 200°C for 15 min. The DIN abrasion values according to ISO standard 4649, expressed as a relative volume decrease 10 with respect to the standard composition, were also measured.

15 As can be seen from the data given in Table 2, the composition according to the present invention, which is free of conventional crosslinking agents, makes it possible to obtain a crosslinked product whose properties are entirely comparable with those which can be obtained from the usual compositions vulcanized with sulphur. The carboxylated polymer can also include 20 large amounts of the epoxidized liquid compound, with the production of rubber compositions which have excellent processability without thereby impairing tensile properties or abradability.

The compositions given in Table 3 were prepared by the same methods used in Examples 1-6. The 10 compositions of Examples 14 and 15 (comparative) use epoxy resins containing only epoxide end groups as

crosslinking agents, while the composition of Example 16 was formulated according to the present invention.

The Mooney ML (1+4) viscosity at 100°C was measured on the non-crosslinked compositions, according to ISO standard 289/1. The compositions were then subjected to MDR rheometric analysis using the same rheometer and under the same conditions as in Examples 1-6. The mechanical properties (according to ISO standard 37), the hardness in IRHD degrees (according to ISO standard 48) and the DIN abrasion (according to ISO standard 4649) were measured on samples of the said compositions crosslinked at 200°C for 15 min. The results are given in Table 3.

Table 3 also shows the dynamic elastic modulus values (E') measured at 23°C and at 70°C using an Instron dynamic machine, in traction-compression according to the following method. A test sample of the crosslinked material, of cylindrical shape (length = 25 mm; diameter = 14 mm), preloaded in compression up to a longitudinal deformation of 10% relative to the initial length, and kept at a preset temperature (23°C or 70°C) throughout the test, was subjected to a dynamic sinusoidal deformation of amplitude \pm 3.33% relative to the length under pre-loading, with a frequency of 100 Hz.

 Vulcanox® 4020 (Bayer): anti-fatigue agent (TMQ).

- 29 -

As can be seen, compared with the compositions in which the carboxylated polymer is crosslinked with epoxy resins containing only epoxide end groups, the compositions according to the invention make it possible to obtain rubber compositions of improved processability (lower Mooney viscosity) and crosslinked products in which improved elastic properties (in particular higher elongation at break) are accompanied by lower hardness.

In addition, the crosslinked compositions according to the present invention show very limited variation in the dynamic elastic modulus as the temperature varies, this variation being appreciably less than that encountered in the compositions crosslinked with epoxy resins. This property indicates a lower "thermoplasticity" of the crosslinked compositions according to the present invention, i.e. essentially constant elastic performance qualities over a wide temperature range, and is of fundamental importance when using the compositions in the manufacture of tyres.

EXAMPLES 17-18

The following were prepared using the same open mixer as in Examples 1-6:

- a composition having, as polymer base, a polymer carboxylated according to a standard procedure for vulcanization with sulphur (see "The Vanderbilt Rubber Handbook" - 1978 edition, page 534) (Comparative Example 17);

- an analogous composition devoid of sulphur or derivatives thereof and comprising an epoxidized oil according to the present invention (Example 18).

The compositions are given in Table 4. In the composition of Example 17, cumarone/indene resin, trioctyl phthalate and stearic acid act as processing

- 30 -

coadjuvants and plasticizers, while 6PPD is an anti-ageing additive (Santoflex® 13 from Monsanto) and MBTS is a vulcanization accelerator (2-mercaptobenzothiazole disulphide - Vulkacit Merkapto® from Bayer).

5 The compositions thus prepared were subjected to MDR rheometric analysis at 170°C for 30 min and at 200°C for 30 min, according to the method given for Examples 1-6. The results are given in Table 4. The optimum crosslinking conditions for the two
10 compositions were determined from the curves thus obtained: 10 min at 170°C for the composition of Example 17 (comparative), 15 min at 200°C for the composition of Example 18 (invention).

15 Mechanical properties, IRHD hardness, DIN abrasion and dynamic elastic modulus (E') at 23°C and 70°C were measured on samples of the abovementioned compositions crosslinked under the optimum conditions, according to the methods given above. For completeness, the same measurements were carried out on the compositions of Example 17 crosslinked at 200°C for 15
20 min. The results are given in Table 5.

5 By comparing the data given in Table 5, it can be noted that the compositions according to the present invention make it possible to obtain, under optimum crosslinking conditions, a crosslinked material which has excellent mechanical properties and low 10 abradability, with dynamic elastic modulus values which are relatively independent of the temperature, and thus thermoplasticity lower than analogous compositions crosslinked with sulphur.

EXAMPLES 19-21

15 For the purpose of evaluating the properties of the crosslinked compositions according to the present invention relative to conventional compositions for tread bands vulcanized with rubber, three different compositions were prepared containing silica as 20 reinforcing filler, using a Banbury mixer with tangential rotors and having a volume equal to 1.5 l.

In Example 19 (comparative), the composition had a typical composition for tread bands vulcanized with sulphur, as described in Patent EP-501,227. In accordance with the teachings of that patent, for the 5 purpose of optimizing the dispersion of silica and the reaction between the coupling agent (silane) and silica, the composition was prepared by means of a multi-step thermomechanical processing method: a first 10 step of mechanical mixing of the polymer base, the filler and the processing coadjuvants until a maximum temperature exceeding 145°C was reached, a step of cooling down to a temperature below 60°C, and a second 15 step of mechanical mixing until a maximum temperature exceeding 145°C was reached, in which step the other components of the composition (except for the crosslinking system) were added. Finally, the crosslinking system was added with mixing at a temperature below 100°C.

On the other hand, the compositions of Examples 20 20-21 (invention) were prepared in a Banbury mixer in a single passage, with a rotor speed of 65 rpm and a temperature of the mixer-cooling water of about 40°C.

The Mooney viscosity ML (1+4) at 100°C was measured on the non-crosslinked compositions, according 25 to ISO standard 289/1. The compositions were then subjected to MDR rheometric analysis using the same rheometer and under the same conditions as in Examples 1-6. The optimum crosslinking conditions were determined on the basis of the rheometric analysis, 30 i.e. 10 min at 170°C for the comparative composition (Example 19) and 15 min at 200°C for the compositions according to the invention (Examples 20-21).

The mechanical properties (according to ISO standard 37) and the hardness in IRHD degrees at 23°C 35 and at 100°C (according to ISO standard 48) were

measured on samples of the abovementioned compositions crosslinked under the optimum conditions. The dynamic elastic properties of the samples at 0°C and at 70°C were also evaluated by measurement in traction-compression according to the method described for Examples 14-16. The results are given in Table 6. The dynamic elastic properties are expressed in terms of E' and tan delta (loss factor) at 0°C and at 70°C. As is known, the tan delta value is calculated as the ratio between the viscous modulus (E'') and the elastic modulus (E'), both determined by means of the above dynamic measurements.

S-SBR: solution butadiene-styrene copolymer, with a styrene content equal to 20% by weight and a content of vinyl groups equal to 60% by weight (product Buna VSL® 5025-1 HM from Bayer);

5 BR: polybutadiene (product Europrene Neocis® from Enichem);

X50S: silane coupling agent comprising 50% by weight of carbon black and 50% by weight of bis(3-triethoxysilylpropyl) tetrasulphide (produced by Degussa);

10 CBS: accelerating agent (N-cyclohexyl-2-benzothiazylsulphenamide - product Santocure® from Monsanto);

DPG: accelerating agent (diphenylguanidine from Monsanto).

15 From the data given in Table 6, it is clear that the compositions according to the present invention make it possible to obtain a crosslinked product which has properties similar to those which can be obtained by crosslinking a conventional tread band composition with sulphur. The following can also be noted for the compositions crosslinked according to the present invention:

20 25 - a value of tan delta at 0°C, which, as is known, is an index for wet grip, which is higher and thus better than that obtained with the reference composition;

30 35 - a value of E' at 70°C, which, as is known, is an index for stability of the tread band on curves under "dry handling" conditions, which is higher and thus indicates a better response of the tyre to stresses on curves than that which can be obtained with the reference composition.

It is also important to note that, for substantially equivalent performance qualities, the composition formulation achieved an appreciable

simplification compared with that of a conventional composition (from 11 to 4 ingredients), with obvious advantages for industrial production. In particular, besides not containing a system vulcanized with 5 sulphur, the compositions according to the invention, when filled with silica, do not require the presence of a coupling agent for the silica or a complex thermomechanical processing method in order to obtain a good dispersion and compatibilization of the filler in 10 the polymer matrix.

EXAMPLES 22-24 (comparative)

The composition according to Example 20 was compared with analogous compositions in which the epoxidized soybean oil was replaced with an epoxidized 15 elastomeric polymer (epoxidized natural rubber) having high molecular weight, optionally as a mixture with aromatic oil to improve the processability.

The compositions were prepared in an open mixer according to the method given for Examples 1-6. The 20 Mooney ML (1+4) viscosity at 100°C was measured on the non-crosslinked compositions, according to ISO standard 289/1. The compositions were then subjected to MDR rheometric analysis using the same rheometer and under the same conditions as in Examples 1-6. The mechanical 25 properties (according to ISO standard 37), the hardness in IRHD degrees (according to ISO standard 48) and the dynamic properties (E', tan delta) at 0°C and at 70°C were measured according to the method given above on samples of the abovementioned compositions crosslinked 30 at 200°C for 15 min. The compositions and the results are given in Table 7.

5

Epoxyprene® ENR 50: epoxidized natural rubber containing 50 mol% of epoxide groups and having an average molecular weight of greater than 100,000 (produced by Guthrie).

- 39 -

From the results given in Table 7, it can be seen that:

- 5 - the Mooney viscosity values for the comparative compositions are extremely high, exceeding the maximum limit of the measuring instrument; thus, processability of these compositions is very poor (this fact is demonstrated by the rheometric curves, in which the ML values for the comparative compositions are high);
- 10 - the comparative crosslinked compositions have inferior tensile properties, and in particular low values of elongation at break;
- 15 - the hardness values of the comparative crosslinked compositions are high, even with small amounts of filler, thus making them totally unsuitable for the manufacture of tread bands;
- 20 - the dynamic performance qualities of the comparative compositions are inferior, in particular as regards the tan delta values at 0°C, which were not determined since they exceeded the maximum limit of the measuring instrument.
